

**VERIFICATION OF TRANSLATION**

I, Shinichi MIZOI, 1-9-23-203, Kamijujo Kita-ku, Tokyo 114-0034, Japan, hereby state that I am fluent in the English language and in the Japanese language. I hereby verify that the attached English language translation of the Japanese language patent application entitled

REGULATOR FOR FUEL CELL

is a true and complete translation to the best of my knowledge and belief.

Dated this 10th day of December, 2003

By

Shinichi MIZOI

REGULATOR FOR FUEL CELL

BACKGROUND OF THE INVENTION

Field of the Invention:

5 The present invention relates to a regulator for use with a fuel cell for supplying an anode of a fuel cell stack with a fuel (hydrogen) as a reactant gas under a pressure depending on the pressure of an oxidizing agent (air) which is given as a signal pressure.

10 Description of the Related Art:

 Heretofore, solid polymer membrane fuel cell have a stack of cells (hereinafter referred to as a fuel cell stack) each comprising an anode and a cathode and a solid polymer electrolyte membrane interposed between the anode and the cathode. When hydrogen is supplied as a fuel to the anode and air is supplied as an oxidizing agent to the cathode, hydrogen ions are generated at the anode by a catalytic reaction. The hydrogen ions move through the solid polymer electrolyte membrane to the cathode. Electric power is generated in the fuel cell by the electrochemical reaction.

25 The fuel cell system includes an air compressor for supplying air as a reactant gas to the cathodes of the fuel cell stack and a pressure control valve for supplying hydrogen as a reactant gas to the anodes of the fuel cell stack under a pressure depending on the pressure of air which is given as a signal pressure. The pressure of the

reactant gas supplied to the anodes with respect to the pressure of the reactant gas supplied to the cathodes is adjusted to a predetermined pressure for thereby achieving a predetermined power generation efficiency, and the flow rate of the reactant gas supplied to the fuel cell stack is controlled to obtain a desired fuel cell output.

The applicant of the present application has proposed a gas pressure reducing valve for use in a fuel gas supply device, as disclosed in Japanese laid-open patent publication No. 2002-182751 and Japanese laid-open patent publication No. 11-270717.

SUMMARY OF THE INVENTION

It is a general object of the present invention to provide a regulator suitable for use with fuel cells.

A major object of the present invention is to provide a regulator for use with fuel cells which is not required to deliver a fuel gas from a secondary port when unnecessary, thereby preventing the fuel gas from being wasted and saving power, unlike a normally open regulator.

Another object of the present invention is to provide a regulator for use with fuel cells which is capable of preventing air and a fuel gas from being mixed with each other.

Still another object of the present invention is to provide a regulator for use with fuel cells which is capable of regulating the pressure of a fuel gas delivered from a

secondary port to a pressure that is two to four times the pressure of an air serving as a pilot pressure, and of being applied to various ejectors.

Yet another object of the present invention is to provide a regulator for use with fuel cells which is capable of regulating the pressure of a fuel gas delivered from a secondary port to a pressure that is three times the pressure of an air serving as a pilot pressure.

Yet still another object of the present invention is to provide a regulator for use with fuel cells in which a fluid is supplied to the regulator at a constant pressure, and the regulator is capable of reducing a pressure change at the time the flow rate of the fluid supplied to a secondary port is increased, thus providing desirable pressure vs. flow rate characteristics.

A further object of the present invention is to provide a regulator for use with fuel cells which is free of abrupt cross-sectional area changes and is capable of suppressing self-excited oscillations.

A still further object of the present invention is to provide a regulator for use with fuel cells which is capable of preventing a valve head from being inclined on a valve seat.

A yet further object of the present invention is to provide a regulator for use with fuel cells which is capable of achieving good slidability in a sliding region of an outer circumferential surface of a guide member and a guide

sleeve.

The above and other objects, features, and advantages of the present invention will become more apparent from the following description when taken in conjunction with the accompanying drawings in which preferred embodiments of the present invention are shown by way of illustrative example.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a block diagram of a fuel cell system which incorporates a regulator for fuel cells according to an embodiment of the present invention;

FIG. 2 is a vertical cross-sectional view of the regulator with a valve which is closed under normal conditions;

FIG. 3 is a vertical cross-sectional view of the regulator with the valve which is open when the regulator is supplied with a pilot pressure; and

FIG. 4 is a graph showing pressure vs. flow rate characteristics which represent the magnitudes of pressure changes when a flow rate is changed, and the fluid is supplied to the regulator at a constant pressure.

DESCRIPTION OF THE PREFERRED EMBODIMENT

FIG. 1 is a block diagram of a fuel cell system 200 which incorporates a regulator for fuel cells according to an embodiment of the present invention. The fuel cell system 200 is mounted on a vehicle such as an automobile or

the like.

5 The fuel cell system 200 includes a fuel cell stack 202 having a stack of cells each comprising an anode, a cathode, and a solid polymer electrolyte membrane such as a solid polymer ion exchange membrane interposed between the anode and the cathode. The fuel cell stack 202 has an anode supplied with a gas mainly containing hydrogen (hereinafter referred to as "hydrogen") as a fuel gas (hereinafter referred to as "fuel" if necessary) and a cathode supplied
10 with air containing oxygen, for example, as an oxidizing agent.

Air is supplied from an oxidizing agent supply 204 to the cathode of through an air supply port 206. An air discharge port 210 is connected to an air discharger 208 for
15 discharging air in the cathode. A hydrogen is supplied from a fuel supply 212 to the anode through a hydrogen supply port 214. A hydrogen discharge port 218 is connected to a hydrogen discharger 216.

20 The fuel cell stack 202 is arranged such that hydrogen ions generated at the anode by a catalytic reaction move through the solid polymer electrolyte membrane to the cathode where they cause an electrochemical reaction with oxygen to generate electric power.

25 To the air supply port 206, there are connected the oxidizing agent supply 204, a heat radiator 220, and a cathode humidifier 222 by an air supply passage. The air discharger 208 is connected to the air discharge port 210 by

an air discharge passage.

To the hydrogen supply port 214, there are connected the fuel supply 212, a pressure controller 224, an ejector 226, and an anode humidifier 228 by a hydrogen supply passage. The hydrogen discharger 216 is connected to the hydrogen discharge port 218 by a circulation passage 230.

The oxidizing agent supply 204 comprises, for example, a supercharger (compressor) and a motor for actuating the supercharger (not shown). The oxidizing agent supply 204 adiabatically compresses air, which is to be used as an oxidizing gas in the fuel cell stack 202, and supplies the compressed air to the fuel cell stack 202. When the air is adiabatically compressed, it is heated. The heated air that is supplied to the fuel cell stack 202 is effective to warm the fuel cell stack 202.

The air supplied from the oxidizing agent supply 204 is set to a certain pressure depending on the load on the fuel cell stack 202 or the amount of depression of an accelerator pedal (not shown), for example, before it is introduced into the fuel cell stack 202. After the air is cooled by the heat radiator 220, to be described below, it is supplied as a pilot pressure through a bypass passage 232 to the pressure controller 224.

The heat radiator 220 comprises an intercooler or the like (not shown), for example, and cools the air supplied from the oxidizing agent supply 204 during normal operation of the fuel cell stack 202 through a heat exchange with

cooling water which flows through a flow passage.

Therefore, the supplied air is cooled to a predetermined temperature and then introduced into the cathode humidifier 222.

5 The cathode humidifier 222 has a water-permeable membrane, for example. The cathode humidifier 222 humidifies the air, which has been cooled to the predetermined temperature by the heat radiator 220, to a certain humidity by passing water from one side of the
10 water-permeable membrane to the other, and supplies the humidified air to the air supply port 206 of the fuel cell stack 202. The humidified air is supplied to the fuel cell stack 202 to keep the ion conductivity of the solid polymer electrolyte membranes of the fuel cell stack 202 in a
15 predetermined state.

 The air discharger 208 connected to the air discharge port 210 of the fuel cell stack 202 has a discharge valve (not shown) which discharges the air into the atmosphere.

20 The fuel supply 212 comprises a hydrogen gas container (not shown) for supplying hydrogen as a fuel to the fuel cells, for example. The fuel supply 212 stores hydrogen that is to be supplied to the anode of the fuel cell stack 202.

25 The pressure controller 224 incorporates a regulator 10 for fuel cells, to be described later, therein. The pressure controller 224 sets a secondary pressure that is the pressure from the outlet of the pressure controller 224

to a pressure within a predetermined range, using the pressure of the air supplied through the bypass passage 232 as a pilot pressure (pilot signal pressure). For example, the pressure controller 224 sets the ratio of the pilot signal pressure to the secondary pressure to a value in the range from about 1 : 2 to about 1 : 4. Therefore, the secondary pressure is set in the range from about 2 to about 4 with respect to the pilot signal pressure set to 1. This ratio range is effective to keep desired circulation pressure and suction characteristics and maximize the performance of the ejector 226 in various experiments conducted on the ejector 226 as described later. Particularly, the ratio of the pilot signal pressure to the secondary pressure is set to 1 : about 3 in the ejector 226 according to the present embodiment.

The ejector 226 comprises a nozzle and a diffuser (not shown). The fuel (hydrogen) supplied from the pressure controller 224 is accelerated when it passes through the nozzle, and ejected toward the diffuser. When the fuel flows at a high speed from the nozzle to the diffuser, a negative pressure is developed in an auxiliary chamber disposed between the nozzle and the diffuser, attracting the fuel discharged from the anode through the circulation passage 230. The fuel and the discharged fuel that are mixed together by the ejector 226 are supplied to the anode humidifier 228. The fuel discharged from the fuel cell stack 202 circulates through the ejector 226.

Therefore, the unreacted gas discharged from the hydrogen discharge port 218 of the fuel cell stack 202 is introduced through the hydrogen passage 230 into the ejector 226. The hydrogen supplied from the pressure controller 224 and the gas discharged from the fuel cell stack 202 are mixed with each other and supplied to the fuel cell stack 202.

The anode humidifier 228 has a water-permeable membrane, for example. The anode humidifier 228 humidifies the fuel, which has been delivered from the ejector 226, to a certain humidity by passing water from one side of the water-permeable membrane to the other, and supplies the humidified fuel to the hydrogen supply port 214 of the fuel cell stack 202. The humidified hydrogen is supplied to the fuel cell stack 202 to keep the ion conductivity of the solid polymer electrolyte membranes of the fuel cell stack 202 in a predetermined state.

The hydrogen discharger 216, which has a discharge control valve, not shown, is connected to the hydrogen discharge port 218 of the fuel cell stack 202 by the circulation passage 230. The discharge control valve can be opened and closed depending on an operating state of the fuel cell stack 202 for discharging excessive water (mainly liquid water) in a discharged gas which has been separated by a reservoir tank, not shown.

The regulator 10 for fuel cells according to the present embodiment, which is incorporated in the pressure

controller 224 of the fuel cell system 200, is shown in
FIGS. 2 and 3.

5 The regulator 10 includes a body 16 having a primary
port 12 for introducing hydrogen supplied from the fuel
supply 212 and a secondary port 14 for regulating the
pressure of the hydrogen introduced from the primary port 12
to a predetermined pressure and delivering the pressure-
regulated hydrogen to the ejector 226. The body 16 is made
up of a first block 18a, a second block 18b, and a third
10 block 18c that are stacked and integrally joined together.
The body 16 has a space 20 defined therein which houses
therein a valve mechanism 24 for selectively opening and
closing a fluid passage 22 that provides fluid communication
between the primary port 12 and the secondary port 14.

15 The first block 18a has a hole defined in the bottom
thereof, and a valve head guide member 28 is received in the
hole and joined to the first block 18a by a bolt 30 with an
O-ring 26 interposed therebetween. The valve head guide
member 28 has an integral cylindrical guide sleeve 32
20 projecting a predetermined length in the axial direction of
the space 20. The valve head guide member 28 has a central
hole defined therein in which there is threaded a closure
member 36 closing a back pressure chamber 36, to be
described later, with an O-ring 38 interposed between the
25 valve head guide member 28 and the closure member 36. The
closure member 36 has a recess 40 having a rectangular
cross-sectional shape which is defined in an end thereof.

The recess 40 serves to receive a tool or the like, not shown, for threading the closure member 36 into the central hole in the valve head guide member 28 from outside of the regulator 10.

5 The valve head guide member 28 and the first block 18a are formed separately independently of each other, and can easily be assembled together by the bolt 30. Since the valve head guide member 28 and the first block 18a are formed as separate members, a fluoro-resin coating can be
10 applied to the valve head guide member 28 without affecting the material and surface treatment of the body 16 (the first block 18a). If the valve head guide member 28 and the first block 18a were integrally formed and a fluoro-resin coating were applied to the integral assembly, then when the
15 integral assembly is baked, an alumite film applied to the surface of the first block 18a of the body 16 would be broken.

 As the substantially central hole is defined in the valve head guide member 28 and subsequently closed by the
20 closure member 36, a fluoro-resin coating can easily be applied by spraying to an inner wall surface of the guide sleeve 32 of the valve head guide member 28. The fluoro-resin coating thus applied is uniform and stable. After the fluoro-resin coating is applied by spraying to the
25 inner wall surface of the guide sleeve 32, the closure member 36 can easily be mounted in the hole in the valve head guide member 28.

The valve mechanism 24 includes a rod 42 extending in the axial direction of the body 16 and a guide member 46 fitted over the rod 42 and having an integral valve head 44 projecting radially outwardly.

5 The valve mechanism 24 also has a large-diameter first diaphragm 50 coupled to an end of the rod 42 by a first retaining mechanism 48 and a small-diameter second diaphragm 54 disposed between the first diaphragm 50 and the valve head 44 and coupled to the rod 42 by a second retaining
10 mechanism 52.

 The first diaphragm 50 and the second diaphragm 54 have respective pressure-bearing areas whose ratio is set to a value in the range from about 2 : 1 to about 4 : 1 for the reasons described above. Preferably, the ratio of the
15 pressure-bearing areas of the first diaphragm 50 and the second diaphragm 54 is set to about 3 : 1 for regulating the pressure of hydrogen (secondary pressure) delivered from the secondary port 14 to a value that is three times the air pressure as the pilot pressure, thereby to keep desired
20 circulation pressure and suction characteristics of the ejector 226 connected to the secondary port 14 and used in the present embodiment, and to maximize the performance of the ejector 226.

 The rod 42 has an integral stopper 58 formed on an
25 intermediate portion thereof and comprising four fingers bent into an L-shaped cross section and angularly spaced at angular intervals of about 90 degrees in the circumferential

direction. The stopper 58 serves as part of the second retaining mechanism 52.

5 The guide member 46 comprises an elongate hollow cylinder having a first communication hole 62 which communicates with a hollow region 60 defined in the guide member 46. The valve head 44 which projects a predetermined length radially outwardly is integrally formed with an end of the hollow cylinder of the guide member 46. The guide member 46 has an elongate portion extending below the valve head 44 and performing a guiding function for preventing the 10 valve head 44 from being inclined when the valve head 44 is seated on a valve seat 64.

15 The guide member 46 is of a reduced weight as it has the hollow region 60 and the first communication hole 62, and hence suffers reduced self-excited oscillations and is subject to reduced sliding resistance. The portion of the guide member 46 which performs its guiding function and the guide sleeve 32 are coated with a fluororesin coating to achieve good slidability in a sliding region of the guide member 46 and the guide sleeve 32 for increased durability. 20 An annular rubber member 68 is applied to the area of the valve head 44 which is to be seated on the valve seat 64.

25 An O-ring 70 is mounted in an annular groove defined in the outer circumferential surface of the guide member 46 near the valve head 44, and a Y-gasket 72 is mounted in an annular groove defined in the outer circumferential surface of the guide member 46 at a position spaced from the O-ring

70 remotely from the valve head 44. The O-ring 70 and the Y-gasket 72 which are held in contact with the guide sleeve 32 for performing a sealing function are spaced a predetermined distance from each other for providing a desired sliding resistance to suppress self-excited oscillations.

When the guide member 46 is displaced along the guide sleeve 32 as the O-ring 70 and the Y-gasket 72 slide against the latter, the guide member 46 is linearly guided while being displaced in unison with the rod 42, allowing the valve head 44 to be seated on the valve seat 64 without being inclined with respect to the valve seat 64.

The Y-gasket 72 mounted on the guide member 46 remotely from the valve head 44 poses a sliding resistance that is slightly smaller than if the Y-gasket 72 were replaced with an O-ring. The O-ring 70 disposed closely to the valve head 44 and the Y-gasket 72 disposed remotely from the valve head 44 jointly provide a desired sliding resistance. The desired sliding resistance may also be achieved by using a sliding member, e.g., a bearing or the like, not shown, instead of the Y-gasket 72. The guide sleeve 32 may have a hole, not shown, and the O-ring 70 may be replaced with a sliding member such as a bearing or the like. In such a modification, the Y-gasket 72 may be replaced with an O-ring.

The guide member 46 has an annular recess defined in the outer circumferential surface thereof between the O-ring

70 and the Y-gasket 72, providing an annular space 74 between the guide member 46 and the guide sleeve 32. The annular space 74 is held in communication with the axially extending first communication hole 62 through a hole 76 defined in the guide member 46 substantially perpendicularly to the first communication hole 62.

The annular space 74 defined between the O-ring 70 and the Y-gasket 72 which are spaced a predetermined distance from each other and communicating with the first communication hole 62 develops a negative pressure between the O-ring 70 and the Y-gasket 72, preventing the O-ring 70 and the Y-gasket 72 from sticking to the inner wall surface of the guide sleeve 32 (from being attracted thereto by a sealing action). Therefore, the guide member 46 is given desired slidability with respect to the guide sleeve 32 of the valve head guide member 28. The present invention is not limited to the hole 76 defined in communication with the first communication hole 62, but a hole, not shown, may be defined in the guide sleeve 32 of the valve head guide member 28 to prevent a sealed state from being developed between the O-ring 70 and the Y-gasket 72.

The back pressure chamber 34 that is surrounded by the guide sleeve 32 and the closure member 36 is defined in the end of the guide member 46 whose outer circumferential surface is sealed by the O-ring 70 and the Y-gasket 72. The back pressure chamber 34 is effective to reduce the pressure imposed on the valve head 44 for improved pressure vs. flow

rate characteristics. Stated otherwise, the force tending to urge the valve head 44 in a direction away from the valve seat 64 under a regulated secondary pressure and the force tending to urge the valve head 44 in a directed to be seated on the valve seat 64 with a fluid under pressure introduced into the back pressure chamber 34 cancel each other, thus reducing the pressure imposed on the valve head 44.

The back pressure chamber 34 is held in communication with an aspirator chamber 80, to be described later, through the first communication hole 62 which extends a predetermined length axially in the rod 42, and a second communication hole 78 crossing the first communication hole 62 substantially perpendicularly thereto.

A coiled first spring 56 is disposed around the guide member 46 and has an end engaging the valve head 44 and the other end engaging in an annular recess defined in the body valve guide member 28. The valve head 44 is normally biased to be seated on the valve seat 64 under the spring force of the first spring 56. The spring force of the first spring 56 is set to a value greater than the spring force of a coiled second spring 84 which is disposed in a pilot chamber 82, to be described later.

Since the spring force of the first spring 56 overcomes the spring force of the second spring 82 which normally urges the valve head 44 in a direction away from the valve seat 64, the valve mechanism is of the normally closed type in which the valve head 44 is seated on the valve seat 64 in

a normal condition where no pilot pressure is applied.
Since the valve mechanism is of the normally closed type,
hydrogen is not delivered from the secondary port 14 when
unnecessary, and hence is prevented from being wasted for
5 saving power.

The first spring 56 which functions as a return spring
may possibly affect the pressure ratio 1 : 3 between air and
hydrogen. In view of such a concern, the ratio of the
pressure-bearing areas of the large-diameter first diaphragm
10 50 and the small-diameter second diaphragm 54 should be set
to a value in the range from 3.1 : 1 to 3.2 : 1, most
preferably be set to 3.16 : 1. If the ratio of the
pressure-bearing areas of the first diaphragm 50 and the
second diaphragm 54 is set to the ratio 3.16 : 1 which has
15 been determined on experimental data, then a reduction in
the pressure of hydrogen due to the resistive force of the
first spring 56 is corrected, keeping an appropriate
pressure ratio between air and hydrogen.

A valve seat member 66 which includes the valve seat 64
20 for seating thereon the valve head 44 of the guide member 46
is disposed on an inner wall surface of the first block 18a,
and an O-ring 86 having a sealing function is disposed
between the valve seat member 66 and the inner wall surface
of the first block 18a. The valve seat member 66 is crimped
25 in place on an annular ridge formed on the first block 18a.
The valve seat member 66 has a tapered surface 88
progressively spreading in a direction away from the valve

head 44 and surrounding the rod 42 out of contact therewith.

A space between the outer circumferential surface of the rod 42 and the tapered surface 88 of the valve seat member 66 functions as the fluid passage 22. The fluid
5 passage 22 has its cross-sectional area progressively increased by the tapered surface 88 which progressively spreads upwardly away from the valve seat 64, and hence is free of abrupt cross-sectional area changes and is capable of suppressing self-excited oscillations.

10 An aspirator holder 90 having a through hole through which the rod 42 extends is screwed to a step formed in an upper portion of the first block 18a. The aspirator chamber 80 is defined between the aspirator holder 90 and the second diaphragm 54. To the aspirator holder 90, there is
15 connected a nozzle 94 communicating with the aspirator chamber 80 and having a suction hole 92 directed toward the secondary port 14.

The fluid passage 22 which is progressively enlarged toward the secondary port 14 is defined between a slanted
20 surface of the aspirator holder 90 and the tapered surface 88 of the valve seat 66. Therefore, the fluid passage 22 is free of abrupt cross-sectional area changes and is capable of suppressing self-excited oscillations.

25 An O-ring 98 is mounted in an annular groove defined in the outer circumferential surface of the rod 42, and held in contact with the surface of the through hole in the aspirator holder 90 to provide a sealing function to keep

the aspirator chamber 80 hermetically sealed. The aspirator chamber 80 is held in communication with the first communication hole 62 which extends axially through the rod 42 and the back pressure chamber 34 near the guide member 46 through the second communication hole 78 extending perpendicularly to the axis of the rod 42.

The retaining mechanism 48 comprises a first upper retainer 100 held against an upper surface of the first diaphragm 50 and a first lower retainer 102 held against a lower surface of the first diaphragm 50. The first upper and lower retainers 100, 102 are mounted on the rod 42 at their respective central holes. The first diaphragm 50 has an outer circumferential edge portion which is not retained by the first upper and lower retainers 100, 102, but sandwiched between the second block 18b and the third block 18c.

The second retaining mechanism 52 comprises a second upper retainer 104 held against an upper surface of the second diaphragm 54 and a second lower retainer 106 held against a lower surface of the second diaphragm 54. Only the second upper retainer 104 is mounted on the rod 42, and the second lower retainer 106 is integrally formed with the rod 42. The second diaphragm 54 has an outer circumferential edge portion which is not retained by the second upper and lower retainers 104, 106, but sandwiched between the first block 18a and the second block 18b.

After the second upper retainer 104, the first lower

retainer 102, and the first upper retainer 100 are successively stacked on the second lower retainer 106 that is integrally formed with the rod 42, they are fastened to the rod 42 by a wave washer 110 and a nut 112.

5 The stopper 58 which is bent downwardly into an L-shaped cross section is formed on the outer circumferential edge of the second lower retainer 106. The stopper 58 comprises four fingers angularly spaced at angular intervals of about 90 degrees in the circumferential direction. When
10 the first diaphragm 50, the second diaphragm 54, and the rod 42 are displaced downwardly in unison with each other under a pilot pressure supplied to the pilot chamber 82, the stopper 58 abuts against an upper surface of the aspirator holder 90, limiting the displacement of the rod 42 thereby
15 to perform its stopping function.

 An atmospheric chamber 114 that is closed by an inner wall surface of the second block 18b is defined between the first diaphragm 50 and the second diaphragm 54, and is held in communication with the atmosphere through a passage, not
20 shown. An annular recess 118 for allowing a bent outer circumferential edge 116 of the first lower retainer 102 to enter therein is defined in the inner wall surface of the second block 18b. The dimension of a region where the bent outer circumferential edge 116 enters the annular recess 118
25 is thus reduced, making smaller the axial size of the regulator.

 The pilot chamber 82 is defined above the first

diaphragm 50 and surrounded by an inner wall surface of the third block 18c. The pilot chamber 82 is supplied with a pilot pressure through a pilot port, not shown. The pilot chamber 82 is closed by a large-diameter first adjustment screw (first adjustment member) 122 which is threaded into an internally threaded hole in the third block 18c with an O-ring 120 interposed therebetween, and a small-diameter second adjustment screw (second adjustment member) 126 which is threaded into an internally threaded hole that is defined centrally in the first adjustment screw 122.

The first adjustment screw 122 has an adjustment knob 128 having a hexagonal cross-sectional shape, and the second adjustment screw 126 has an adjustment cavity 130 having a hexagonal cross-sectional shape.

The second spring 84 is disposed in the pilot chamber 82, and has an end engaging a spring retainer 132 and the other end engaging a leaf spring 134 which is to be described later. The first adjustment screw 122 can make coarse adjustment of the spring force of the second spring 84, and the second adjustment screw 126 can make fine adjustment of the spring force of the second spring 84.

By thus adjusting the spring force of the second spring 84 in two stages with the first and second adjustment screws 122, 126, the spring force of the second spring 84 can be adjusted in a large adjustment range, providing a good spring load capability with small spring load changes.

A cylindrical bushing 136 of stainless steel is mounted

on the inner wall surface of the third block 18c which defines the pilot chamber 82. The leaf spring 134 is held in frictional contact with an inner circumferential surface of the bushing 136 for imparting sliding resistance to the first diaphragm 50.

The leaf spring 134 comprise an annular portion 134a mounted on an annular land of the first upper retainer 100, a plurality of legs 134b raised upwardly perpendicularly to the annular portion 134a and angularly spaced at predetermined intervals in the circumferential direction, and a plurality of curved portions 134c disposed respectively on the distal ends of the legs 134b. The leaf spring 134 is coated with a diamond-like carbon coating or the like to provide an appropriate contact resistance between the bushing 136 and the curved portions 134c for a desired sliding resistance.

Since the bushing 136 of stainless steel is mounted on the inner wall surface of the third block 18c and has its inner circumferential surface held in contact with the curved portions 134c of the leaf spring 134, the inner circumferential surface of the bushing 136 is protected for increased durability.

Operation and advantages of the regulator 10 for fuel cells according to the present invention will be described below.

In the present embodiment, the spring force of the first spring 56 disposed below the valve head 44 is set to a

value greater than the spring force of the second spring 84 which is disposed in the pilot chamber 82 above the valve head 44. Therefore, the valve mechanism is closed with the valve head 44 seated on the valve seat 64 in a normal condition where no pilot pressure is applied to the pilot chamber 82.

Consequently, according to the present embodiment, no hydrogen needs to be delivered from the secondary port 14 when unnecessary unlike a normally open regulator where the valve head 44 is spaced a predetermined distance from the valve seat 64 in a normal condition. As a result, according to the present embodiment, hydrogen as a fuel is prevented from being wasted for saving power.

When the oxidizing agent supply 204 is actuated in response to a movement of an accelerator pedal or the like, pilot air is introduced through the bypass passage 232 and a pilot port, not shown, into the pilot chamber 82. The pilot air introduced into the pilot chamber 82 acts to press the first diaphragm 50 downwardly. The first diaphragm 50, the second diaphragm 54, and the valve head 44 which are coupled together by the rod 42 are displaced downwardly in unison with each other, and the valve head 44 is spaced from the valve seat 64. At this time, the stopper 58 integral with the rod 42 abuts against a flat upper surface of the aspirator holder 90, limiting the displacement of the rod 42.

When hydrogen supplied from the primary port 12 passes

through the gap between the valve head 44 and the valve seat 64, the pressure thereof is reduced to a desired pressure corresponding to the pilot pressure. The pressure-regulated hydrogen then passes through the fluid passage 22, and is thereafter discharged from the secondary port 14 to the ejector 226.

Inasmuch as the ratio of the pressure-bearing area of the first diaphragm 50 on which the pilot pressure acts and the pressure-bearing area of the second diaphragm 54 on which hydrogen introduced into the aspirator chamber 80 is set to a value in the range from about 2 : 1 to about 4 : 1, most preferably set to 3.16 : 1, the pressure of the hydrogen discharged from the secondary port 14 can be set to a value which is three times the air pressure as the pilot pressure. Therefore, the ejector 226 connected to the secondary port 14 can keep desired circulation pressure and suction characteristics, and have its performance maximized.

According to the present embodiment, the regulator 10 has two diaphragms, i.e., the first diaphragm 50 which flexes under the pressure of air supplied as the pilot pressure and the second diaphragm 54 which flexes under the pressure of hydrogen flowing through the fluid passage 22, with the atmospheric chamber 114 defined between the first diaphragm 50 and the second diaphragm 54. Therefore, even when either the first diaphragm 50 or the second diaphragm 54 has its durability degraded, the air and the hydrogen are prevented from being mixed with each other. Even if air or

hydrogen finds its way into the atmospheric chamber 114, it can be discharged into the atmosphere through the non-illustrated passage.

According to the present embodiment, when the hydrogen discharged from the secondary port 14 is increased in quantity, the pressure in the aspirator chamber 80 becomes lower than the pressure (secondary pressure) discharged from the secondary port 14 due to a suction that occurs through the suction hole 92 of the nozzle 94 that is directed toward the secondary port 14. Since the back pressure chamber 34 and the aspirator chamber 80 are held in communication with each other through the hollow region 60, the first communication hole 62, and the second communication hole 78 that are defined in the rod 42, the pressure in the back pressure chamber 34 is equalized with the pressure the aspirator chamber 80, and becomes lower than the secondary pressure discharged the secondary port 14. According to the present embodiment, therefore, the pressure in the back pressure chamber 34 may be lower than would be if the back pressure chamber 34 and the fluid passage 22 connected to the secondary port 14 communicated with each other.

Pressure vs. flow rate characteristics when the flow rate Q of a fluid under pressure is changed under a constant pressure P_1 are shown in FIG. 4. In FIG. 4, a linear characteristic curve A represents pressure vs. flow rate characteristics plotted when only the back pressure chamber 34 is provided. A linear characteristic curve B represents

pressure vs. flow rate characteristics plotted when the back pressure chamber 34 communicates with the fluid passage 22 connected to the secondary port 14. A linear characteristic curve C represents pressure vs. flow rate characteristics plotted when the back pressure chamber 34 communicates with the aspirator chamber 80.

As can be understood from FIG. 4, a pressure change ΔP that is caused when the flow rate Q of the fluid under pressure is increased to a flow rate Q_1 under the constant pressure P_1 is the greatest for the linear characteristic curve A that is plotted when only the back pressure chamber 34 is provided. The pressure change ΔP for the linear characteristic curve B that is plotted when the back pressure chamber 34 communicates with the fluid passage 22 connected to the secondary port 14 is smaller than the pressure change ΔP for the linear characteristic curve A. The pressure change ΔP for the linear characteristic curve C that is plotted when the back pressure chamber 34 communicates with the aspirator chamber 80 is the smallest, i.e., smaller than the pressure changes ΔP for the linear characteristic curves A, B.

According to the present embodiment, therefore, since the back pressure chamber 34 and the aspirator chamber 80 are held in communication with each other through the hollow region 60, the first communication hole 62, and the second communication hole 78 that are defined in the rod 42, the pressure change ΔP is prevented from unduly increasing even

when the flow rate of the fluid under pressure increases, thus minimizing a pressure loss. As a result, the regulator according to the present embodiment provides good pressure vs. flow rate characteristics.
